

Exercise 2.4: Django Views and Templates

Reflection Questions

1. Do some research on Django views. In your own words, use an example to explain how Django views work.

Python Views are Python Functions that allow users to send a request and their request is returned as an image, document or URL. For example, I want to login to the Career Foundry website, the login request is made and the login.py is returned.

2. Imagine you're working on a Django web development project, and you anticipate that you'll have to reuse lots of code in various parts of the project. In this scenario, will you use Django function-based views or class-based views, and why?

In this scenario I would use the class-based views because it allows you to re-use the code across several app and so reducing duplication and saving time.
